

Weekly route reliability review notes

This note goes with the service workbook for the operations meeting. The page should help the service planning lead decide which route corridor needs attention first, not reproduce the whole service log.

Use posted service records from the current route list as the working base. Forecast schedules, board rollups, event notes, weather notes, dispatcher summaries, and older comparison rows sometimes travel with the packet because they help explain the week. They are useful context, but the final measures should come from the posted service records and the route lookup.

Timing

The current review window is October through December 2026. When you describe whether reliability pressure is getting better or worse, compare that window with July through September 2026.

Measures

Reliability gap means scheduled trips less on-time trips. Gap rate is the reliability gap divided by scheduled trips. Crowding pressure is review-window crowding reports per 10,000 typical monthly boardings from the route lookup.

Attention score

For the service attention score, index each signal across the current route corridors first, then blend the indexed signals using the mix below. Round scores, rates, and percentage-point movement to one decimal for the visual.

Signal used in the review	Share
Current reliability gap rate	40%
Change versus baseline	25%
Crowding pressure	20%
Rider sensitivity	15%

Corridors at 65 or above are in the top attention band. If two rounded scores land in the same place, show the corridor with the larger review-window reliability gap first, then higher rider sensitivity, then route name.
